Managing Python Versions

1. In your terminal, identify which python versions are installed on your system. What command(s) did you use to do this? What versions are installed?

2. Install python versions 3.12.7 and 3.13.0 to your system (this may take a couple of minutes). Set version 3.12.7 as the default version. What command(s) did you use to do this? How can you tell this is the new default?

3. Change to the `pyenv_lab` directory. What is the currently set python version? Does the set version match the default version you set previously? Why or why not?
